Structural timber —
Determination of
characteristic values of
mechanical properties
and density

The European Standard EN 384:2004 has the status of a
British Standard

ICS 79.040
National foreword

This British Standard is the official English language version of EN 384:2004. It supersedes BS EN 384:1995 which is withdrawn.

The UK participation in its preparation was entrusted to Technical Committee B/518, Structural timber, which has the responsibility to:

— aid enquirers to understand the text;
— present to the responsible international/European committee any enquiries on the interpretation, or proposals for change, and keep the UK interests informed;
— monitor related international and European developments and promulgate them in the UK.

A list of organizations represented on this committee can be obtained on request to its secretary.

Cross-references

The British Standards which implement international or European publications referred to in this document may be found in the BSI Catalogue under the section entitled “International Standards Correspondence Index”, or by using the “Search” facility of the BSI Electronic Catalogue or of British Standards Online.

This publication does not purport to include all the necessary provisions of a contract. Users are responsible for its correct application.

Compliance with a British Standard does not of itself confer immunity from legal obligations.

Summary of pages

This document comprises a front cover, an inside front cover, the EN title page, pages 2 to 15 and a back cover.

Structural timber - Determination of characteristic values of mechanical properties and density

Bois de structure - Détermination des valeurs caractéristiques des propriétés mécaniques et de la masse volumique

Bauholz für tragende Zwecke - Bestimmung charakteristischer Werte für mechanische Eigenschaften und Rohdichte

This European Standard was approved by CEN on 20 February 2003.

CEN members are bound to comply with the CEN/CENELEC Internal Regulations which stipulate the conditions for giving this European Standard the status of a national standard without any alteration. Up-to-date lists and bibliographical references concerning such national standards may be obtained on application to the Central Secretariat or to any CEN member.

This European Standard exists in three official versions (English, French, German). A version in any other language made by translation under the responsibility of a CEN member into its own language and notified to the Central Secretariat has the same status as the official versions.

CEN members are the national standards bodies of Austria, Belgium, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Iceland, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Norway, Poland, Portugal, Slovakia, Slovenia, Spain, Sweden, Switzerland and United Kingdom.

Foreword

This document (EN 384:2004) has been prepared by Technical Committee CEN/TC 124 “Timber structures”, the secretariat of which is held by DS.

This European Standard shall be given the status of a national standard, either by publication of an identical text or by endorsement, at the latest by July 2004, and conflicting national standards shall be withdrawn at the latest by July 2004.

This document supersedes EN 384:1995.

According to the CEN/CENELEC Internal Regulations, the national standards organizations of the following countries are bound to implement this European Standard: Austria, Belgium, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Iceland, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Norway, Poland, Portugal, Slovakia, Slovenia, Spain, Sweden, Switzerland and United Kingdom.
Introduction

In this revised edition the method for determining characteristic values from tests on small clear specimens is now only permitted for hardwoods. Changes to factor $k_v$ and other minor changes have also been made.

Structural codes can only function effectively if standard methods of determining the mechanical and physical properties exist.

Whilst total accuracy of characteristic values for any defined population is an aim, it is recognized that this is not achievable. A major aim of the procedures given in this standard is to produce characteristic values that are comparable in terms of the populations they represent. It is also important that the standard permits the use of as much existing test data as possible from various sampling and testing techniques.

Where methods are given to permit characteristic values to be determined from a less than ideal amount of structural size test data or from small, clear, defect-free specimen test data, reduction factors to reflect a lower degree of confidence are employed.

This standard covers the stages of population definition, sampling, testing and analysis of data in the determination of characteristic values.
1 Scope

This standard gives a method for determining characteristic values of mechanical properties and density, for
defined populations of timber of visual and/or mechanical strength grades.

A method is also given for checking the strength of a timber sample against its designated value.

The values determined in accordance with this standard for mechanical properties and density are suitable for
assigning grades and species to the strength classes of EN 338.

NOTE For assigning grades and species to the strength classes in EN 338 only three characteristic values, i.e. bending
strength, mean modulus of elasticity parallel to grain and density need to be determined, other properties may be taken from the
table in EN 338.

2 Normative references

This European Standard incorporates by dated or undated reference, provisions from other publications. These
normative references are cited at the appropriate places in the text and the publications are listed hereafter. For
dated references, subsequent amendments to or revisions of any of these publications apply to this European
Standard only when incorporated in it by amendment or revision. For undated references the latest edition of the
publication referred to applies (including amendments).

EN 408:2003, Timber structures - Structural timber and glued laminated timber - Determination of some physical
and mechanical properties.

prEN 14081-1, Timber structures – Strength graded structural timber with rectangular cross section – Part 1:
General requirements.

ISO 3131:1975, Wood - Determination of density for physical and mechanical tests.

3 Terms and definitions

For the purposes of this European Standard, the following terms and definitions apply:

3.1 characteristic value
generally a value that corresponds to a fractile of the statistical distribution of a timber property. For strength
properties, modulus of elasticity and density the fractile is the 5-percentile. For modulus of elasticity, the mean
value is also a characteristic value.

3.2 p-percentile
value for which the probability of getting lower values is p%.

3.3 population
material for which the characteristic values are relevant.

NOTE The population is defined by parameters such as species or species grouping, source and strength grade.

3.4 sample
a number of specimens of one cross section size and from one population.

3.5 small clear test
test to determine mechanical properties of small defect-free specimens.
3.6 specimen
piece of timber for testing.

3.7 thickness
lesser dimension perpendicular to the longitudinal axis of a piece of timber.

3.8 width
greater dimension perpendicular to the longitudinal axis of a piece of timber.

3.9 depth
dimension perpendicular to the longitudinal axis of a timber beam, in the plane of the bending forces.

4 Symbols and abbreviations

\( a_i \) distance between the inner load points of the bending test (in mm)

\( E \) mean modulus of elasticity for one sample (in \( \text{N/mm}^2 \))

\( E_{0,\text{mean}} \) mean characteristic value of modulus of elasticity parallel to grain (in \( \text{N/mm}^2 \))

\( E_{0,05} \) 5-percentile characteristic value of modulus of elasticity parallel to grain (in \( \text{N/mm}^2 \))

\( E_{90,\text{mean}} \) mean characteristic value of modulus of elasticity perpendicular to grain (in \( \text{N/mm}^2 \))

\( f \) strength property

\( f_{c,0,k} \) characteristic value of compression strength parallel to grain (in \( \text{N/mm}^2 \))

\( f_{c,90,k} \) characteristic value of compression strength perpendicular to grain (in \( \text{N/mm}^2 \))

\( f_k \) characteristic value of strength (in \( \text{N/mm}^2 \))

\( f_{m,k} \) characteristic value of bending strength (in \( \text{N/mm}^2 \))

\( f_{\text{mean}} \) sample mean value of strength (in \( \text{N/mm}^2 \))

\( f_{r} \) 5-percentile ranked test value (in \( \text{N/mm}^2 \))

\( f_{0,0,k} \) characteristic value of tensile strength parallel to grain (in \( \text{N/mm}^2 \))

\( f_{t,90,k} \) characteristic value of tensile strength perpendicular to grain (in \( \text{N/mm}^2 \))

\( f_{05} \) 5-percentile value for each sample (in \( \text{N/mm}^2 \))

\( f_{05} \) the mean value of \( f_{05} \) for several samples (in \( \text{N/mm}^2 \))

\( f_{v,k} \) characteristic value of shear strength (in \( \text{N/mm}^2 \))

\( G_{\text{mean}} \) mean characteristic value of shear modulus (in \( \text{N/mm}^2 \))

\( h \) depth of a bending specimen or width of a tension specimen (in mm)

\( k_g \) factor used for determining characteristic values of tension and compression parallel to grain and shear

\( k_h \) factor for adjusting \( f_k \) when \( h \) is different from 150 mm

\( k_l \) factor for adjusting length;
5 Mechanical properties determined from full-size specimens

5.1 Sampling

Samples shall be selected from the population of timber graded visually or by machine to the requirements given in prEN 14081-1. The population shall be capable of being identified at all stages of production and supply, including the construction site.

The test material shall be representative of the population. The timber shall represent the timber source, sizes, and quality that will be graded in production. Each sample shall be from one source.

NOTE 1 Any known or suspected difference in the mechanical properties of the population distribution due to growth regions, sawmills, tree size or method of conversion should be represented within the number of samples selected, by a similar proportion to their frequency in the population. This should be the major influence in determining the number and size of samples.

The number of specimens in each sample shall be not less than 40.

NOTE 2 Where samples are small and/or few in number the characteristic values will be penalized, see 5.4.

The cross section size of specimens shall be the same within a sample, but different for other samples, reflecting the range of sizes to which the grading rules are applicable. However, if the size effect for the grading rule has been established for a similar species, then fewer sizes may be tested.

Test specimens for shear, tension perpendicular to grain and compression perpendicular to grain strengths are comparatively small and therefore shall be free of strength reducing characteristics, but must represent the full range of growth areas, density and rates of growth.

5.2 Testing

Testing shall be carried out in accordance with EN 408:2003. Except for the strength properties of shear, tension perpendicular to grain and compression perpendicular to grain, a critical section shall be selected in each piece of timber. This section is the position at which failure is expected to occur, based on a visual examination and any other information such as measurements from a strength grading machine. The critical section shall be in a position...
that can be tested, e.g., not outside the inner load points in a bending test or in close proximity to the jaws in a tension test. For tests to determine modulus of elasticity, the procedure shall be as given in clause 10 in EN 408:2003 and the critical section shall be positioned between the loading heads. The grade of the piece of timber shall be deemed to be the grade of the critical section.

NOTE 1 Because the method used for determining the 5-percentile values of the strength properties is non-parametric (see 5.3.1), not all specimens in the test samples need to be tested to failure.

For a bending test for strength or modulus of elasticity, the tension edge shall be selected at random.

For a tension test for strength or modulus of elasticity, the timber test length clear of the machine grips shall be nine times the width of the piece.

NOTE 2 Existing data from different test methods or moisture conditions are acceptable provided sufficient information exists to adjust the results to the reference conditions given in 5.3.3. These differences might be in moisture content, test spans or orientation of test specimens. If these data are not available, recommendations for some of these adjustments are given in 5.3.4.

5.3 Analysis of data

5.3.1 Determination of sample 5-percentile

For each sample, a 5-percentile value \( f_{0.05} \) shall be determined from the equation: \( f_{0.05} = f \), where \( f \) is obtained by ranking all the test values for a sample in ascending order. The 5-percentile value is the test value for which 5% of the values are lower or equal. If this is not an actual test value (i.e., the number of test values is not divisible by 20) then interpolation between the two adjacent values is required.

5.3.2 Determination of the sample mean of modulus of elasticity

The sample mean value of modulus of elasticity \( E \) shall be calculated from the following equation, which includes an adjustment to a pure bending modulus of elasticity:

\[
E = \left[ \frac{\sum E_i}{n} \right]^{1.3} - 2690
\]

where

\( E_i \) is the \( i \)'th value of modulus of elasticity (see 5.2) in the range 1 to \( n \) expressed in Newtons per square millimetre (in N/mm\(^2\)).

5.3.3 Reference conditions

5.3.3.1 Moisture content

The reference moisture content shall be consistent with 20°C and 65% relative humidity.

NOTE For most softwoods this corresponds to a moisture content of about 12%.

5.3.3.2 Bending strength

The reference condition corresponds to a depth of 150 mm and to the standard test set-up proportions of third point loading with an overall span of 18 times the specimen depth.

5.3.3.3 Tension strength

The reference condition corresponds to a width of 150 mm. All other requirements are implicit in 5.2.

5.3.4 Adjustment factors

5.3.4.1 General

Each sample 5-percentile or mean value shall be adjusted to the standard reference conditions.
5.3.4.2 Moisture content of the samples

For samples not tested at the reference conditions but having a mean moisture content in the range 10% to 18%, adjustment of the lower 5-percentile or mean to 12% moisture content (or a value shown by test to be more appropriate to the reference conditions for that species), shall be as follows. If other more relevant factors are available from test data, then they shall be used instead.

   a) For bending and tension strength: no adjustment.

   b) For compression parallel to grain strength: 3% change for every percentage point difference in moisture content.

   c) For modulus of elasticity: 2% change for every percentage point difference in moisture content.

   d) For compression parallel to grain strength and modulus of elasticity: the adjustments are carried out so that the properties increase if the data are adjusted from a higher moisture content, and vice versa.

5.3.4.3 Timber size and test length

5-percentiles of bending and tensile strength shall be adjusted to 150mm depth or width by dividing

\[ k_h = \left( \frac{150}{h} \right)^{0.2} \]

Where the bending test arrangement is not as in EN 408:2003 (i.e. span, \( \ell = 18h \) and distance between inner load points, \( a_f = 6h \)) then the 5-percentile bending strength shall be adjusted by dividing by

\[ k_l = \left( \frac{\ell_{es}}{\ell_{et}} \right)^{0.2} \]

where

\( \ell_{es} \) and \( \ell_{et} \) are calculated as follows:

\[ \ell_{es} \text{ or } \ell_{et} = \ell + 5a_f \]

where \( a_f \) and \( \ell \) have the respective values for the standard test procedure and for the test.

5.3.4.4 Other adjustments

If the test methods and/or conditions differ from the reference conditions in any way other than described in 5.3.4.2 and 5.3.4.3, then adjustment factors shall be derived from similar methods and/or conditions and used to adjust the 5-percentile or mean value to the reference conditions.

5.4 Strength properties

The characteristic value of strength \( f_k \) shall be calculated from the equation:

\[ f_k = \bar{f}_{05} k_e k_v \]

where

\( \bar{f}_{05} \) is the mean (in N/mm2) of the adjusted 5-percentile values \( f_{05} \) for each sample, weighted according to the number of pieces in each sample. If \( \bar{f}_{05} \) is greater than the lowest adjusted sample value of \( f_{05} \) times 1.2
then either the reference population shall be redefined to eliminate the lowest value, or $f_{05}$ shall be given the value of 1.2 times the extreme low value of $f_{05}$;

$k_s$ is a factor to adjust for the number of samples and their size and shall be obtained from Figure 1.

$k_v$ is a factor to allow for the lower variability of $f_{05}$ values between samples for machine grades in comparison with visual grades;

for machine grades with $f_{mk}$ greater than 30 N/mm$^2$, and all visual grades, $k_v = 1.0$

for machine grades with $f_{mk}$ equal to or less than 30 N/mm$^2$, $k_v = 1.2$.

Factors $k_s$ and $k_v$ shall not be used to calculate characteristic values of shear, tension perpendicular to grain and compression perpendicular to grain strengths.

Figure 1 The effects of the number of samples and their size on the factor $k_s$

5.5 Modulus of elasticity

After adjusting the value of $E$ for each sample (see 5.3.2) to the reference conditions (see 5.3.4) the characteristic value $E_{0,\text{mean}}$ shall be calculated from the equation:

$$E_{0,\text{mean}} = \frac{\sum E_j n_j}{\sum n_j}$$

where

$n_j$ is the number of specimens in sample $j$;

$E_j$ is the mean value of modulus of elasticity for sample $j$ expressed in Newtons per square millimetre (in N/mm$^2$).
6 Density

The characteristic density shall be calculated from density measurements of samples selected according to 5.1.

The measurements shall be carried out in accordance with 6.1 of ISO 3131:1975. Where the moisture content is higher than 12%, the density shall be decreased by 0.5% for every percentage point difference in moisture content and, where the moisture content is lower than 12%, the density shall be increased by 0.5% for every percentage point difference in moisture content. This assumes that both the mass and volume are measured at the test moisture content. The sample 5-percentile density \( r_{0.05} \) shall be calculated from the equation:

\[
\rho_{0.05} = (\bar{\rho} - 1.65s) \text{ kg/m}^3
\]

where

\( \bar{\rho} \) and \( s \) are the mean and standard deviations respectively of the densities of all specimens in the sample (in kg/m\(^3\)).

Where not all the specimens are tested to failure, the density of each specimen is permitted to be determined from the mass and volume of the whole specimen and adjusted to the density of the small defect-free prisms given in ISO 3131:1975, by dividing by 1.05. This does not include any adjustment for moisture content, which may also be necessary.

The characteristic density \( r_k \) shall be calculated from the equation:

\[
\rho_k = \frac{\sum n_j r_{0.05,j}}{\sum n_j}
\]

where

\( n_j \) is the number of specimens in sample \( j \);
\( r_{0.05,j} \) is the 5-percentile value of density for sample \( j \).

7 Alternative methods of determining mechanical properties

7.1 Bending strength and modulus of elasticity determined from small, clear specimens

This procedure is only permitted for hardwood species.

Factors to determine characteristic values of bending strength and modulus of elasticity may be derived where both small clear and structural size data are available for at least three other species. (It is essential that these species are similar). These factors shall then be derived from ratios of the characteristic values from the structural size data to the mean values of the small clear data. These factors are then permitted to be applied to species where only small, clear data exist.

For the small clear data, the number of specimens in a sample shall be at least 40 taken from at least five trees, and the test method shall be the same in all cases.

Characteristic values determined in this way shall be reduced by multiplying by 0.9.

7.2 Other mechanical properties

7.2.1 General

If no structural size test data are available for the relevant properties, then the characteristic values shall be determined in accordance with 7.2.2 to 7.2.7 from the characteristic values for bending strength, mean modulus of elasticity and density, provided that those values have been determined in accordance with clauses 5, 6, 7 and 8.
7.2.2 Tension and compression parallel to grain strength and shear strength

The characteristic values of tensile strength parallel to grain, \( f_{t,0,k} \), compressive strength parallel to grain, \( f_{c,0,k} \), and shear strength, \( f_{v,k} \), for softwood species, shall be calculated from the following equations:

\[
\begin{align*}
    f_{t,0,k} &= 0.6 f_{m,k} \\
    f_{c,0,k} &= 5(f_{m,k})^{0.45} \\
    f_{v,k} &= \min\left\{ \frac{3.8}{0.2(f_{m,k})^{0.8}} \right\}
\end{align*}
\]

7.2.3 Tension perpendicular to grain strength

The characteristic value of tensile strength perpendicular to grain, \( f_{t,90,k} \), shall be calculated from the equation:

\[
    f_{t,90,k} = \min\left\{ \frac{0.6}{0.0015\rho_k} \right\}
\]

7.2.4 Compression perpendicular to grain strength

The characteristic value of compressive strength perpendicular to grain, \( f_{c,90,k} \), shall be calculated from the equation:

\[
    f_{c,90,k} = \begin{cases} 0.007\rho_k & \text{for softwoods} \\
                      0.015\rho_k & \text{for hardwoods} \end{cases}
\]

7.2.5 Characteristic fifth percentile modulus of elasticity parallel to grain

The characteristic modulus of elasticity parallel to grain \( E_{0,05} \) shall be calculated for softwood species:

\[ E_{0,05} = 0.67 E_{0,\text{mean}} \]

for hardwood species:

\[ E_{0,05} = 0.84 E_{0,\text{mean}} \]

7.2.6 Mean modulus of elasticity perpendicular to grain

The mean modulus of elasticity perpendicular to grain \( E_{90,\text{mean}} \) shall be calculated from the equation

for softwood species:  \[ E_{90,\text{mean}} = E_{0,\text{mean}} / 30 \]

for hardwood species:  \[ E_{90,\text{mean}} = E_{0,\text{mean}} / 15 \]

7.2.7 Shear modulus

The mean shear modulus \( G_{\text{mean}} \) shall be calculated from the equation:

\[ G_{\text{mean}} = E_{0,\text{mean}} / 16 \]

8 Mechanical properties for other grades

Where data to determine characteristic values of bending strength, modulus of elasticity and density, in accordance with clauses 5 and 6, are available for only one grade of a species or species group, then characteristic values for other grades of the same species may be determined by applying grade relativity factors. These factors shall be derived from the ratios of characteristic values, determined in accordance with clauses 5 and 6, from at least three other similar species of species groups for which data exist for all the grades required.
9 Verification

To check a stated characteristic value for a given population, a sample of that population conforming to the requirements of 5.1 shall be tested in accordance with 5.2.

For strength properties, the 5-percentile value calculated and adjusted in accordance with 5.3.1 and 5.3.4 shall not be less than the characteristic value multiplied by \( k_q \), given in figure 2, and divided by \( k_v \), given in 5.4.

For modulus of elasticity, the mean value calculated and adjusted in accordance with 5.3.2 and 5.3.4 shall be not less than the characteristic value multiplied by \( k_q \) given in figure 2.

![Figure 1 - Values of factor \( k_q \)](image)

A Bending strength machine graded timber
B All other grades and properties
C Sample size

10 Report

A written report giving details of the population, sampling, testing, analytical procedure and calculations shall be prepared.

Note Where a grade and species is to be considered for listing in EN1912 as meeting the requirements of a strength class, the sample distributions of knot size (at the critical section), rate of growth and density will be required. A sample form to be filled in giving details of the characteristic values is shown in annex A.
EN 1912, Structural timber – Strength classes – Assignment of visual grades and species.

EN 338, Structural timber - Strength classes

prEN 14081-2, Timber structures – Strength graded structural timber with rectangular cross section - Part 2: Machine Grading - Additional requirements for initial type testing

prEN 14081-3, Timber structures - Strength graded structural timber with rectangular cross section - Part 3: Machine Grading - Additional requirements for factory production control
## Annex B (informative)

### Sample form containing characteristic values

Required when applying for grades and species to be assigned to strength classes in EN 1912 (see 10).
